## Background

- bioavailability is considered parameter during drug development. However, it is often unknown during early -mid stages of the drug development process.
- It is a common practice to employ animal models for the *in vivo* determination of oral bioavailability in order to estimate human oral bioavailability of a new drug candidate.
- However there is a poor correlation between animal and human bioavailability[1].

# Aims and objectives

- To develop a Receiver Operating Characteristic (ROC) analysis to evaluate the performance of animal oral bioavailability (F<sub>animal</sub>) data for the qualitative prediction of human oral bioavailability (F<sub>human</sub>).
- To identify the optimum cut off values of high/low F<sub>animal</sub> for the qualitative prediction of F<sub>human</sub> from F<sub>animal</sub> data.

### **Materials and methods**

- Oral bioavailability data for both human and preclinical species (mouse, rat, dog and nonhuman primates (NHP)) for 184 compounds were collated from literature as described elsewhere [1].
- For implementation of the ROC analysis, F<sub>human</sub> was defined as high (≥ 50%) or low (< 50) as shown in **Figure 1**.
- The construction of the ROC curves was implemented in Matlab 2012a by varying the animal threshold (t<sub>A</sub>) for high and low F<sub>animal</sub>, the resulting error rates (**Table 1**) for each t<sub>A</sub> were recorded, and plotted.
- Animal models for the prediction of high and low F<sub>human</sub> were evaluated by the area under the ROC curve (AUC)[2-4].
- Optimal cut off values for the F<sub>animal</sub> were calculated by cost analysis assuming similar cost for false positive (FP) and false negatives (FN) and no net cost for true positives (TP) and true negatives (TN)[2, 4].

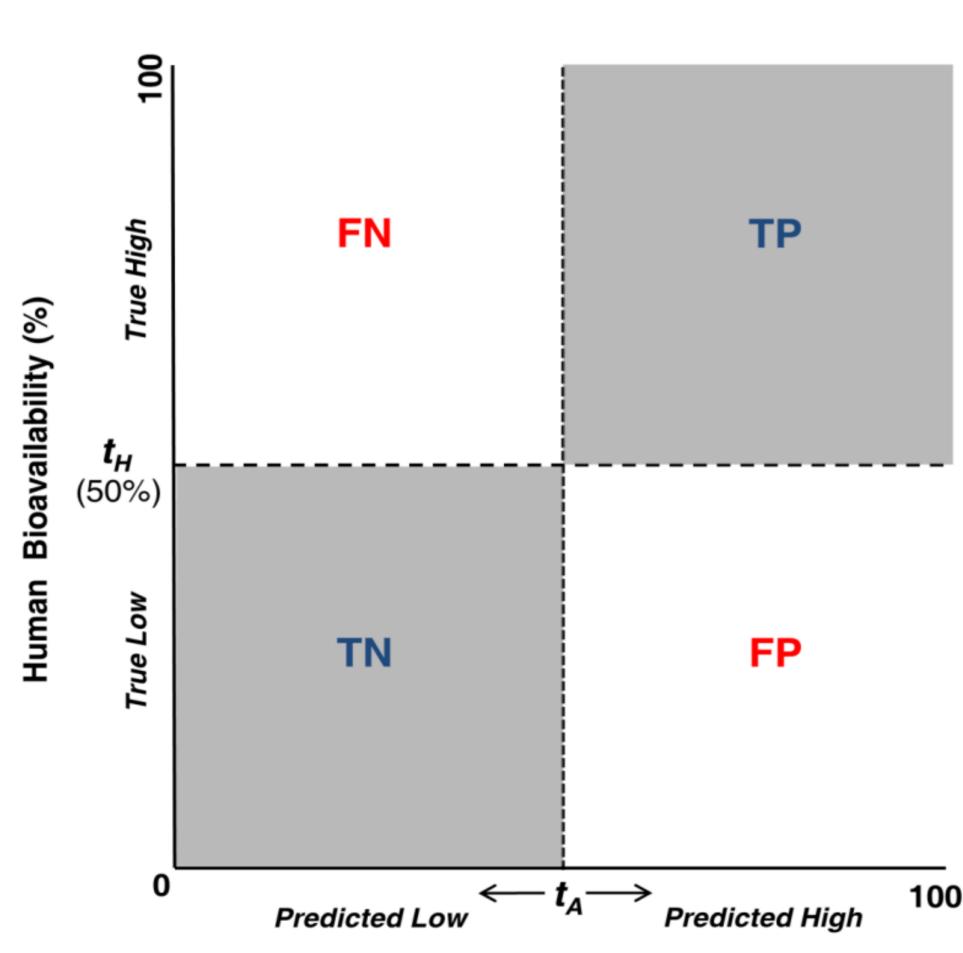

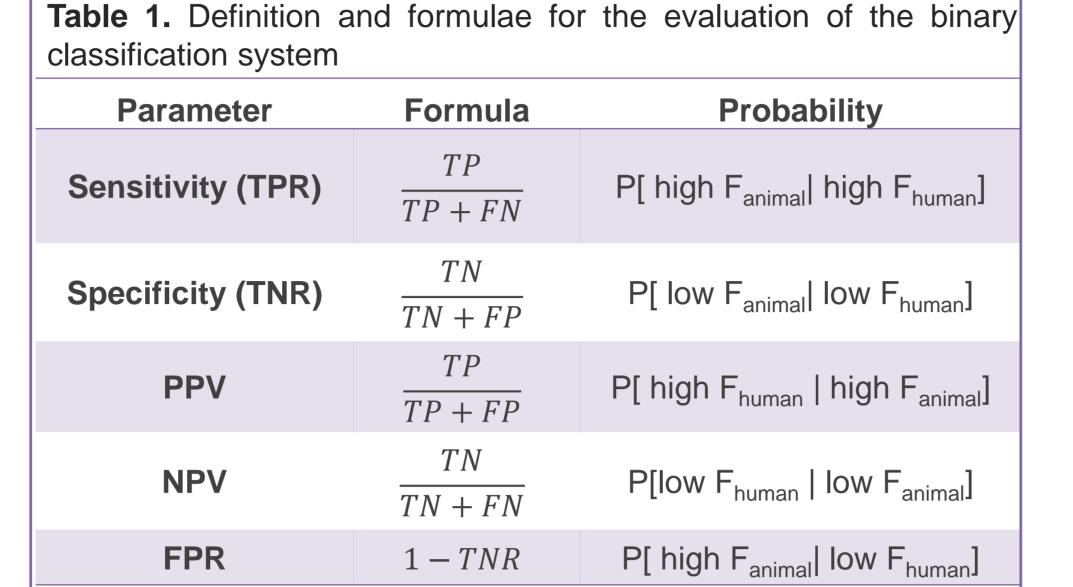

Figure 1. Threshold based predictions of human oral bioavailability from animal data. FN, False negatives; TP, True positives; TN, True negatives; FP, False positive;  $t_A$ , Animal high/low bioavailability threshold;  $t_H$ , human high/low bioavailability threshold.

**Animal Bioavailability (%)** 

# Materials and methods (cont'd)

TPR, true positive rate; TNR, true negative rate; PPV, positive predictive value; NPV, negative predictive value; FPR, false positive rate.

#### Results

- The results from the ROC curve generation are summarized in Table 2.
- When F<sub>animal</sub> was considered for all species combined, the resulting ROC curve AUC was 0.79 (**Figure 2**). Species specific AUC values were 0.82, 0.73, 0.80 and 0.96 for mouse, rat, dog and NHP, respectively (Figure 3).
- All of the preclinical species showed significant improvement in the predictions of F<sub>human</sub> as compared to a random classification (AUC = 0.5).
- Optimum cut off values for F<sub>animal</sub> and the corresponding error rates are summarized in Table 3.

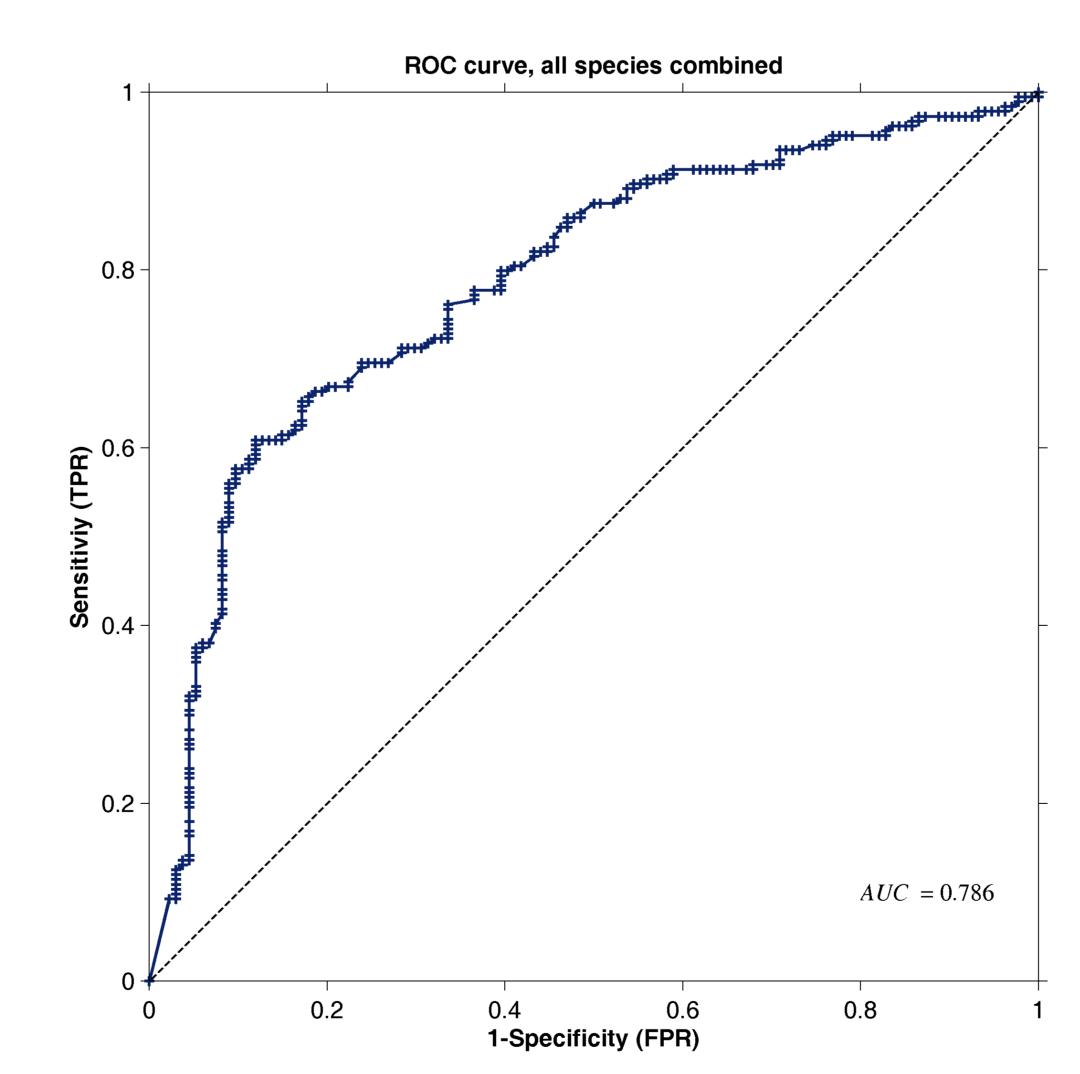

Figure 2. ROC curve for the human versus animal bioavailability dataset for all the preclinical species (mouse, rat, dog and NHP) combined. The dashed line corresponds to the line for random classification, AUC =0.79 for the overall dataset.

Species	AII	Mouse	Rat	Dog	NHP
n	318	30	122	125	41
ROC AUC	0.79	0.82	0.73	0.80	0.96
(95% CI) <sup>a</sup>	(0.73, 0.83)	(0.61, 0.94)	(0.63, 0.82)	(0.70, 0.87)	(0.87, 0.99)

Notes: 'n' is the number of data points; all AUC values were significantly different than 0.5 (p < 0.005); 95% CI was determined by bootstrap (N = 0.005) 10000)

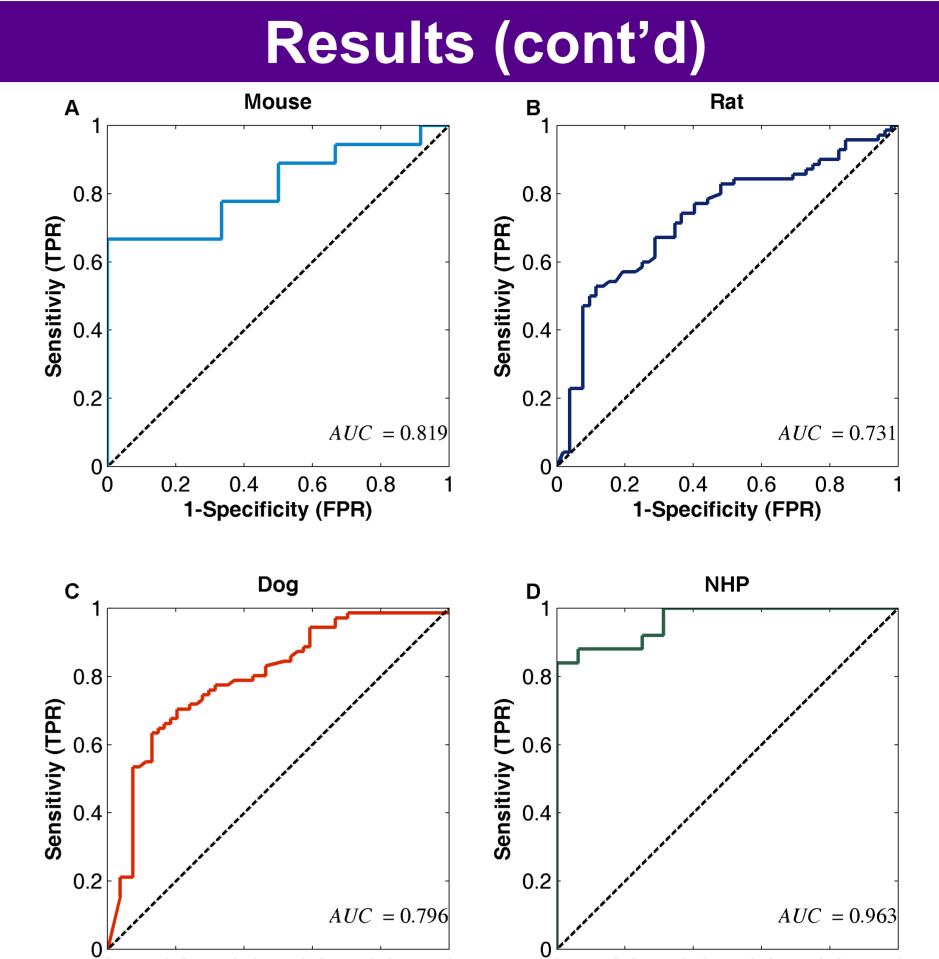

Figure 3. ROC curves for the human versus animal bioavailability dataset by preclinical species. Dashed line corresponds to the line for random classification:

1-Specificity (FPR)

- A. Mouse ROC curve, AUC = 0.82
- B. Rat ROC curve, AUC = 0.73
- C. Dog ROC curve, AUC = 0.80
- D. NHP ROC curve, AUC = 0.94

1-Specificity (FPR)

<b>Table 3.</b> Optimum cut off values for F <sub>animal</sub> derived from cost analysis									
Species	Opt. t <sub>A</sub> (%)	Specificity	Sensitivity	NPV	PPV				
AII	47	0.82	0.66	0.64	0.84				
Mouse	67	1.00	0.67	0.67	1.00				
Rat	22	0.60	0.77	0.66	0.72				
Dog	58	0.80	0.70	0.67	0.82				
NHP	35	1.00	0.84	0.80	1.00				
Opt. t <sub>A</sub> ,Optimum cut off values for F <sub>animal.</sub>									

### Discussion and conclusions

- The results suggest that a value around 50% for F<sub>animal</sub> can predict high and low F<sub>human</sub> with a high sensitivity and specificity.
- Species specific results suggest a similar approach, where NHP shown to be the best prediction. The latter is consistent with the values reported previously for point-wise correlations [1,5,6]. In addition the cut off values are consistent with previous values reported for rat [7,8].
- The resulting cut off values can be employed to make "go/no-go" decisions during development of new drug candidates.
